$1 \quad$ Calculate $y=x^{n}$ ..... 10

[^0]
## 1 Introduction

This package provides two environments, algorithmic and algorithm, which are designed to be used together but may be used separately. The algorithmic environment provides an environment for describing algorithms and the algorithm environment provides a "float" wrapper for algorithms (implemented using algorithmic or some other method at the author's option). The reason that two environments are provided is to allow the author maximum flexibility.

This work may be distributed and/or modified under the conditions of the GNU Lesser General Public License as published by the Free Software Foundation (see the file COPYING included in this package). This package (currently) consists of three files: algorithm.sty, algorithmic.sty and algorithms.tex (the source of this document).

## 2 The algorithmic Environment

Within an algorithmic a number of commands for typesetting popular algorithmic constructs are available. In general, the commands provided can be arbitrarily nested to describe quite complex algorithms. An optional argument to the \begin\{algorithmic\} statement can be used to turn on line numbering } by giving a positive integer indicating the required frequency of line numbering. For example, \begin\{algorithmic\} [5] would cause every fifth line to be } numbered.

### 2.1 The Simple Statement

The simple statement takes the form
\STATE <text>
and is used for simple statements, e.g.

```
\begin{algorithmic}
\STATE $S \leftarrow O$
\end{algorithmic}
would produce
    S\leftarrow0
and with line numbering selected for every line using
```

```
\begin{algorithmic}[1]
\STATE $S \leftarrow 0$
\end{algorithmic}
```

would produce
1: $S \leftarrow 0$

For users of earlier versions of algorithmic this construct is a cause of an incompatibility. In the earlier version, instead of starting simple statements with the \STATE command, simple statements were entered as free text and terminated with $\backslash \backslash$ command. Unfortunately, this simpler method failed to survive the modifications necessary for statement numbering. However, the <br> command can still be used to force a line break within a simple statement.

### 2.2 The if-then-else Construct

The if-then-else construct takes the forms.

```
\IF{<condition>} <text> \ENDIF
\IF{<condition>} <text1> \ELSE <text2> \ENDIF
\IF{<condition1>} <text1> \ELSIF{<condition2>} <text2> \ELSE <text3> \ENDIF
```

In the third of these forms there is no limit placed on the number of $\backslash \operatorname{ELSIF}\{<C>\}$ that may be used. For example,

```
\begin{algorithmic}
\IF{some condition is true}
\STATE do some processing
\ELSIF{some other condition is true}
\STATE do some different processing
\ELSIF{some even more bizarre condition is met}
\STATE do something else
\ELSE
\STATE do the default actions
\ENDIF
\end{algorithmic}
would produce
    if some condition is true then
        do some processing
    else if some other condition is true then
        do some different processing
    else if some even more bizarre condition is met then
        do something else
    else
        do the default actions
    end if
with appropriate indentations.
```

### 2.3 The for Loop

The for loop takes the forms.
\FOR\{<condition>\} <text> \ENDFOR
\FORALL\{<condition>\} <text> \ENDFOR

For example,

```
\begin{algorithmic}
\FOR{$i=0$ to $10$}
\STATE carry out some processing
\ENDFOR
\end{algorithmic}
produces
    for i=0 to 10 do
        carry out some processing
    end for
and
\begin{algorithmic}[1]
\FORALL{$i$ such that $O\leq i\leq 10$}
\STATE carry out some processing
\ENDFOR
\end{algorithmic}
produces
    for all i such that 0\leqi\leq10 do
        carry out some processing
    end for
```

### 2.4 The while Loop

The while loop takes the form.

```
\WHILE{<condition>} <text> \ENDWHILE
```

For example,
\begin\{algorithmic\} }
\WHILE\{some condition holds\}
\STATE carry out some processing \ENDWHILE
\end\{algorithmic\} }

## produces

while some condition holds do carry out some processing
end while

### 2.5 The repeat-until Loop

The repeat-until loop takes the form.
\REPEAT <text> \UNTIL\{<condition>\}

For example,

```
\begin{algorithmic}
\REPEAT
\STATE carry out some processing
\UNTIL{some condition is met}
\end{algorithmic}
produces
    repeat
        carry out some processing
    until some condition is met
```

### 2.6 The Infinite Loop

The infinite loop takes the form.
\LOOP <text> \ENDLOOP
For example,

```
\begin{algorithmic}
\LOOP
\STATE this processing will be repeated forever
\ENDLOOP
\end{algorithmic}
produces
    loop
        this processing will be repeated forever
    end loop
```

### 2.7 The Precondition

The precondition (that must be met if an algorithm is to correctly execute) takes the form.
\REQUIRE <text>
For example,
\begin\{algorithmic\} }
\REQUIRE \$x \neq 0\$ and \$n \geq 0\$
\end\{algorithmic\} }
produces
Require: $x \neq 0$ and $n \geq 0$

### 2.8 The Postcondition

The postcondition (that must be met after an algorithm has correctly executed) takes the form.
\ENSURE <text>
For example,
\begin\{algorithmic\} }
\ENSURE \$x \neq 0\$ and \$n \geq 0\$
\end\{algorithmic\} }
produces
Ensure: $x \neq 0$ and $n \geq 0$

### 2.9 Returning Values

The algorithmic environment offers a special statement for explicitly returning values in algorithms. It has the syntax:
\RETURN <text>
For example,
\begin\{algorithmic\} }
\RETURN \$ ( $\mathrm{x}+\mathrm{y}$ )/2\$
\end\{algorithmic\} }
produces
return $(x+y) / 2$

### 2.10 Printing Messages

Another feature of the algorithmic environment is that it currently provides a standard way of printing values (which is an operation used enough to merit its own keyword). It has the syntax:
\PRINT <text>
For example,
\begin\{algorithmic\} }
\PRINT \texttt\{'‘Hello, World!'’\}
\end\{algorithmic\} }
produces
print '‘Hello, World!'’

### 2.11 Comments

Comments may be inserted at most points in an algorithm using the form.
\COMMENT\{<text>\}
For example,
\begin\{algorithmic\} }
\STATE do something \COMMENT\{this is a comment\}
\end\{algorithmic\} }
produces
do something $\{$ this is a comment $\}$
Because the mechanisms used to build the various algorithmic structures make it difficult to use the above mechanism for placing comments at the end of the first line of a construct, the commands \IF, \ELSIF, \ELSE, \WHILE, \FOR, $\backslash$ FORALL, $\backslash$ REPEAT and $\backslash$ LOOP all take an optional argument which will be treated as a comment to be placed at the end of the line on which they appear. For example,

```
repeat {this is comment number one}
    if condition one is met then {this is comment number two}
        do something
    else if condition two is met then {this is comment number three}
        do something else
    else {this is comment number four}
        do nothing
    end if
until hell freezes over
```

### 2.12 An Example

The following example demonstrates the use of the algorithmic environment to describe a complete algorithm. The following input

```
\begin{algorithmic}
\REQUIRE $n \geq 0$
\ENSURE $y = x^n$
\STATE $y \Leftarrow 1$
\STATE $X \Leftarrow x$
\STATE $N \Leftarrow n$
\WHILE{$N \neq 0$}
\IF{$N$ is even}
\STATE $X \Leftarrow X \times X$
\STATE $N \Leftarrow N / 2$
\ELSE[$N$ is odd]
\STATE $y \Leftarrow y \times X$
\STATE $N \Leftarrow N - 1$
```

```
\ENDIF
\ENDWHILE
\end\{algorithmic\} }
will produce
Require: \(n \geq 0\)
Ensure: \(y=x^{n}\)
    \(y \Leftarrow 1\)
    \(X \Leftarrow x\)
    \(N \Leftarrow n\)
    while \(N \neq 0\) do
        if \(N\) is even then
            \(X \Leftarrow X \times X\)
            \(N \Leftarrow N / 2\)
        else \(\{N\) is odd \(\}\)
            \(y \Leftarrow y \times X\)
            \(N \Leftarrow N-1\)
    end if
end while
which is an algorithm for finding the value of a number taken to a non-negative power.
```

### 2.13 Options

There is a single option, noend that may be invoked when the algorithmic package is loaded. With this option invoked the end statements are omitted in the output. This allows space to be saved in the output document when this is an issue.

### 2.14 Customization

In order to facilitate the use of this package with foreign languages, all of the words in the output are produced via redefinable macro commands. The default definitions of these macros are:

```
\newcommand{\algorithmicrequire}{\textbf{Require:}}
\newcommand{\algorithmicensure}{\textbf{Ensure:}}
\newcommand{\algorithmicend}{\textbf{end}}
\newcommand{\algorithmicif}{\textbf{if}}
\newcommand{\algorithmicthen}{\textbf{then}}
\newcommand{\algorithmicelse}{\textbf{else}}
\newcommand{\algorithmicelsif}{\algorithmicelse\ \algorithmicif}
\newcommand{\algorithmicendif}{\algorithmicend\\algorithmicif}
\newcommand{\algorithmicfor}{\textbf{for}}
\newcommand{\algorithmicforall}{\textbf{for all}}
\newcommand{\algorithmicdo}{\textbf{do}}
```

```
\newcommand{\algorithmicendfor}{\algorithmicend\\algorithmicfor}
\newcommand{\algorithmicwhile}{\textbf{while}}
\newcommand{\algorithmicendwhile}{\algorithmicend\\algorithmicwhile}
\newcommand{\algorithmicloop}{\textbf{loop}}
\newcommand{\algorithmicendloop}{\algorithmicend\ \algorithmicloop}
\newcommand{\algorithmicrepeat}{\textbf{repeat}}
\newcommand{\algorithmicuntil}{\textbf{until}}
\newcommand{\algorithmicprint}{\textbf{print}}
\newcommand{\algorithmicreturn}{\textbf{return}}
```

In addition, the formatting of comments is implemented via a single argument command macro which may also be redefined. The default definition is
\newcommand\{\algorithmiccomment\}[1] \{<br>{\#1<br>}\}
and another option that may be interesting for users familiar with C-like languages is to redefine the comments to be
[1]\{//\#1\}
Comments produced this way would be like this:

$$
i \leftarrow i+1 / / \text { Increments } i
$$

This second way to present comments may become the default in a future version of the package.

## 3 The algorithm Environment

### 3.1 General

When placed within the text without being encapsulated in a floating environment algorithmic environments may be split over a page boundary greatly detracting from their appearance. In addition, it is useful to have algorithms numbered for reference and for lists of algorithms to be appended to the list of contents. The algorithm environment is meant to address these concerns by providing a floating environment for algorithms. For example, the input text

```
\begin{algorithm}
\caption{Calculate $y = x^n$}
\label{alg1}
\begin{algorithmic}
\REQUIRE $n \geq 0 \vee x \neq 0$
\ENSURE $y = x^n$
\STATE $y \Leftarrow 1$
\IF{$n < 0$}
\STATE $X \Leftarrow 1 / x$
\STATE $N \Leftarrow -n$
\ELSE
```

```
Algorithm 1 Calculate \(y=x^{n}\)
Require: \(n \geq 0 \vee x \neq 0\)
Ensure: \(y=x^{n}\)
    \(y \Leftarrow 1\)
    if \(n<0\) then
        \(X \Leftarrow 1 / x\)
        \(N \Leftarrow-n\)
    else
        \(X \Leftarrow x\)
        \(N \Leftarrow n\)
    end if
    while \(N \neq 0\) do
        if \(N\) is even then
            \(X \Leftarrow X \times X\)
            \(N \Leftarrow N / 2\)
        else \(/ / N\) is odd
            \(y \Leftarrow y \times X\)
            \(N \Leftarrow N-1\)
        end if
    end while
```

```
\STATE $X \Leftarrow x$
\STATE $N \Leftarrow n$
\ENDIF
\WHILE{$N \neq 0$}
\IF{$N$ is even}
\STATE $X \Leftarrow X \times X$
\STATE $N \Leftarrow N / 2$
\ELSE[$N$ is odd]
\STATE $y \Leftarrow y \times X$
\STATE $N \Leftarrow N - 1$
\ENDIF
\ENDWHILE
\end{algorithmic}
\end{algorithm}
```

produces Algorithm 1 which is a slightly modified version of the earlier algorithm for determining the value of a number taken to an integer power. In this case, provided the power may be negative provided the number is not zero.

The command \listofalgorithms may be used to produce a list of algorithms as part of the table contents as shown at the beginning of this document. An auxiliary file with a suffix of .loa is produced when this feature is used.

### 3.2 Options

The appearance of the typeset algorithm may be changed by use of the options: plain, boxed or ruled during the loading of the algorithm package. The default option is ruled.

The numbering of algorithms can be influenced by providing the name of the document component within which numbering should be recommenced. The legal values for this option are: part, chapter, section, subsection, subsubsection or nothing. The default value is nothing which causes algorithms to be numbered sequentially throughout the document.

### 3.3 Customization

In order to facilitate the use of this package with foreign languages, methods have been provided to facilitate the necessary modifications.

The title used in the caption within algorithm environment can be set by use of the standard \floatname command which is provided as part of the float package which was used to implement this package. For example,
\floatname\{algorithm\}\{Procedure\}
would cause Procedure to be used instead of Algorithm within the caption of algorithms.

In a manner analogous to that available for the built in floating environments, the heading used for the list of algorithms may be changed by redefining the command listalgorithmname. The default definition for this command is

```
\newcommand{\listalgorithmname}{List of Algorithms}
```

[^0]:    *Sincere thanks go to the original maintainer of this package, Peter Williams, and for being kind enough to allow me to continue with his quite useful work.
